

Email Helper

The Email Helper provides some assistive handlers for working with Email. For a more robust email solution, see revlgniter's [Email Library](#).

Loading this Helper

This helper is loaded using the following code:

```
rigLoadHelper "email"
```

The following handlers are available:

rigValidEmail("email")

Checks if an email is a correctly formatted email. Note, that this doesn't actually prove the email will recieve mail, simply that it is a validly formed address.

It returns TRUE/FALSE

```
rigLoadHelper "email"

if rigValidEmail("email@some site.com") is TRUE then
    put "email is valid" into gData["emailCheck"]
else
    put "email is not valid" into gData["emailCheck"]
end if
```

rigSendEmail("recipient", "subject", "message", "cc", "bcc")

Sends an email using Mail. For a more robust email solution, see revlgniter's [Email Library](#).

It returns TRUE/FALSE

Note: The sender field appears as "<username@domain.com>" in default configurations. It's the account name and host name of the sending user.
